

# Module 1: AI for Channel Decoding

- You will learn:
  - How to use colab
  - Basics of channel coding
  - Support vector machine
  - Deep learning
- Grading:
  - Syndrome Decoding, 20% ML decoding 10%
  - Classification with support vector machine 20%
  - Deep Learning 20%
  - Mini project 20%
  - Report (no more than 10 pages) 10%

# Error Correction Codes

# Terminology

- Message: Sequence of bits representing your data (link to the website)
- Codeword: Sequence of bits forming your QR code

- Example:

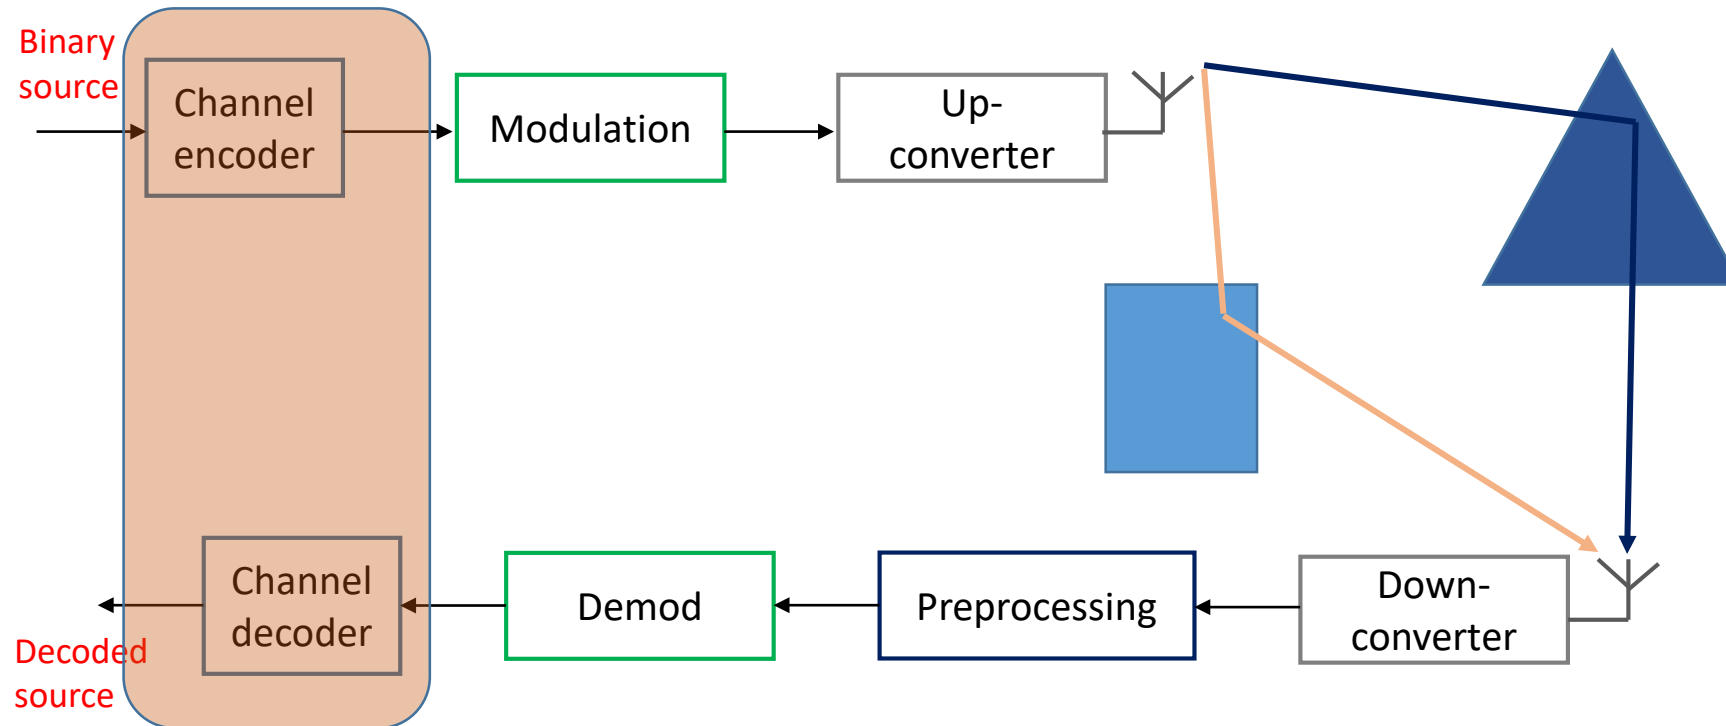

- Message = 1 1 0 1

- Codeword = 1 1 0 1 0 1 0

← These bits are added for error correction

It is everywhere!!! Even in string theory!!!

# A digital communication system over wireless channel

- Channel enc/dec allows error correction by adding redundancy

How it works? How to create those bits?

Index: 1 2 3 4 5 6 7  
Codeword: 1 1 0 1 1 0 0

The last 3 bits are added such that  
inside every circle the number of 1s are even

Suppose 1 bit is erased, we can fix it by  
checking the parity of each circle

Index: 1 2 3 4 5 6 7  
Codeword: 0 1 0 1 ? ? ?

It's your turn

What if 2 bits are erased?

Index: 1 2 3 4 5 6 7  
Codeword: 1 1 0 1 0 1 0

It can also correct 1 bit flip

Suppose 1 bit is flipped, we can fix it by flipping 1 bit to meet all constraints

Index: 1 2 3 4 5 6 7  
Codeword: 1 1 0 1 1 0 0

It can also correct 1 bit flip

Suppose 1 bit is flipped, we can fix it by flipping 1 bit to meet all constraints

# $(n, k)$ -Linear Block Codes

- $k$ -bit message  $\mathbf{m}$ ,  $n$ -bit codeword  $\mathbf{c}$
- Relationship:  $\mathbf{c} = \mathbf{mG}$
- The code  $C$  contains all ( $2^k$  in total) such codewords
  - $C$  is the row space of  $\mathbf{G}$  ( $k \times n$ )
  - Call it a generator matrix
- There exists  $\mathbf{H}$  ( $n - k \times n$ ) such that  $\mathbf{cH}^T = \mathbf{Hc}^T = \mathbf{0}$ 
  - Rows of  $\mathbf{H}$  span the nullspace of  $\mathbf{G}$
  - Call it a parity check matrix

# $(7,4)$ -Hamming Codes

- 4-bit message  $\mathbf{m}$ , 7-bit codeword  $\mathbf{c}$
- Relationship:  $\mathbf{c} = \mathbf{mG}$

- $$\mathbf{G} := \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{pmatrix}$$

- $$\mathbf{H} := \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix}$$

# System Model

- When transmit, we map coded bits to baseband signal
- Binary phase shift keying (BPSK) for sending the bit  $c_i$

$$x_i = \sqrt{P}(2c_i - 1), \quad \mathbf{x} = [x_1, \dots, x_n]$$

- Additive white Gaussian noise (AWGN) channel

$$y_i = x_i + w_i, \quad w_i \sim N(0, \sigma^2), \quad \mathbf{y} = [y_1, \dots, y_n]$$

# BER in Uncoded System

- Detection of  $x_i$  from  $y_i$

$$\hat{x}_i = \text{sign}(y_i) \quad \text{and} \quad \hat{r}_i = (\hat{x}_i + 1)/2$$

- Error if  $\hat{x}_i \neq x_i$
- Bit error rate:  $p_e = \sum 1(\{\hat{x}_i \neq x_i\})/n$

# Maximum Likelihood Decoding

MLD: 
$$\hat{\mathbf{c}} = \underset{\mathbf{c} \in \mathcal{C}}{\operatorname{argmin}} ||\mathbf{y} - \mathbf{x}||^2$$

- This is optimal in AWGN channel with equiprobable inputs
- Complexity is very high, especially when  $k$  is large
  - Need to check  $2^k$  codewords

# Syndrome Decoding

- First make a hard decision

$$\hat{x}_i = \text{sign}(y_i) \quad \text{and} \quad \hat{r}_i = (\hat{x}_i + 1)/2$$

- Construct the standard array
- Compute the syndrome  $\hat{\mathbf{r}}\mathbf{H}^T = \mathbf{s}$
- Decide  $\hat{\mathbf{e}} = \text{coset leader}(\mathbf{s})$
- Decode to  $\hat{\mathbf{c}} = \mathbf{r} + \hat{\mathbf{e}}$

# Standard Array

$\underline{c}_1 = 0$	$\underline{c}_2$	...	$\underline{c}_i$	...	$\underline{c}_{2^k} \leftarrow \text{losset}(0)$
$\underline{e}_2$	$\underline{c}_2 + \underline{e}_2$	...	$\underline{c}_i + \underline{e}_2$	...	$\underline{c}_{2^k} + \underline{e}_2 \leftarrow \text{losset}(\underline{e}_2 H^T)$
$\underline{e}_3$	$\underline{c}_2 + \underline{e}_3$	...	$\underline{c}_i + \underline{e}_3$	...	$\underline{c}_{2^k} + \underline{e}_3$
$\vdots$	$\vdots$		$\vdots$		$\vdots$
$\underline{e}_j$	$\underline{c}_2 + \underline{e}_j$	...	$\underline{c}_i + \underline{e}_j$	...	$\underline{c}_{2^k} + \underline{e}_j \leftarrow \text{losset}(\underline{e}_j H^T)$
$\vdots$					$\vdots$
$\underline{e}_{2^{n-k}}$	$\underline{c}_2 + \underline{e}_{2^{n-k}}$	...	$\underline{c}_i + \underline{e}_{2^{n-k}}$	...	$\underline{c}_{2^k} + \underline{e}_{2^{n-k}} \leftarrow \text{losset}(\underline{e}_{2^k} H^T)$

# Decoding via Learning

- Decoding is nothing but **classification**
- $(n,k)$ -linear block code has  $2^k$  classes
- We can generate a lot of training data  $(\mathbf{y}, \mathbf{c})$
- This is a supervise, batch, passive, and statistical learning
